## COMPOSITION AND AGGREGATIVE STATE OF PRODUCTS OF TITANIUM DIOXIDE HEATED IN AN ARGON MEDIUM

**G. K. Moiseev<sup>1</sup> and A. L. Ivanovskii<sup>1</sup>**

Translated from *Steklo i Keramika*, No. 4, pp. 13–15, April, 2006.

The thermodynamic modeling methods are used to calculate the compositions of a condensed medium taking into account the existence of solid and liquid solutions of  $\text{TiO}_2$ ,  $\text{TiO}$ ,  $\text{Ti}_2\text{O}_3$ ,  $\text{Ti}_3\text{O}_5$ , and  $\text{Ti}_4\text{O}_7$ , as well as partial pressures of  $\{\text{TiO}_2\}$ ,  $\{\text{TiO}\}$ ,  $\{\text{Ti}\}$ ,  $\{\text{O}_2\}$ , and  $\{\text{O}\}$  formed in heating initial titanium dioxide in an argon medium under a pressure of  $9.8066 \times 10^{-2}$  MPa in the temperature interval of 300–2485 K. The obtained results can be useful for the high-temperature synthesis of complex ceramics with the participation of titanium dioxide and for analysis of the composition of ceramics.

Titanium dioxide is widely used as an initial component in the production of diverse types of ceramics that are promising materials for contemporary technologies. Such materials include complex oxide ceramics, glass ceramics, various ceramic composites, nanoceramics, etc. [1–3].

One of the main techniques in the synthesis of complex types of ceramics is the sintering of oxide mixtures. This process, as a rule, is implemented in nonequilibrium conditions, either in air, or in an atmosphere containing oxygen. Detailed studies of the compositions of such materials produced at different temperatures are often missing. In particular, it is believed [4] that  $\text{TiO}_2$  retains a constant composition until its transition to a liquid state.

However, it cannot be excluded that chemical transformations occurring in heat treatment of mixtures containing  $\text{TiO}_2$  may produce other types of titanium oxides which, in turn, are capable of participating in the formation of the composition and functional properties of target products.

The purpose of the present study is the thermodynamic analysis of products formed in heating  $\text{TiO}_2$  in a wide temperature range:  $\Delta T = 300–2485$  K.

In modeling products of  $\text{TiO}_2$  thermal treatment we proceeded from the following assumptions.

It is known that the main condensed phases in the  $\text{Ti}–\text{O}$  system are five oxides, of which the most high-melting is  $\text{TiO}_2$  with a melting point of 2185 K. The melting point of the other oxides are (K): 2110 for  $\text{Ti}_2\text{O}_3$ , 2050 for  $\text{Ti}_3\text{O}_5$ , 2030 for  $\text{TiO}$ , and 1960 for  $\text{Ti}_4\text{O}_7$  [5].

The initial condensed medium was  $\text{TiO}_2$ ; to prevent the effect of the gaseous phase, the computer experiment was performed in an argon medium under isobaric conditions: pressure  $9.8066 \times 10^{-2}$  MPa.

In heat-treating titanium dioxide we expected the possibility of formation of solid and liquid solutions of the initial  $\text{TiO}_2$  and other titanium oxides:  $\text{TiO}$ ,  $\text{Ti}_2\text{O}_3$ ,  $\text{Ti}_3\text{O}_5$ , and  $\text{Ti}_4\text{O}_7$ .

Taking into account the melting temperatures of titanium oxides, we considered six systems for which the following condensed media were specified:

system I,  $\Delta T = 300–1960$  K – solid solution of five titanium oxides;

system II,  $\Delta T = 1960–2030$  K – solid solution ( $\text{TiO}_2 + \text{TiO} + \text{Ti}_3\text{O}_5 + \text{Ti}_2\text{O}_3$ ) and liquid  $\text{Ti}_4\text{O}_7$  phase;

system III,  $\Delta T = 2030–2050$  K – solid solution ( $\text{TiO}_2 + \text{Ti}_3\text{O}_5 + \text{Ti}_2\text{O}_3$ ) and liquid solution ( $\text{Ti}_4\text{O}_7 + \text{TiO}$ );

system IV,  $\Delta T = 2050–2110$  K – solid solution ( $\text{TiO}_2 + \text{Ti}_2\text{O}_3$ ) and liquid solution ( $\text{Ti}_4\text{O}_7 + \text{TiO} + \text{Ti}_3\text{O}_5$ );

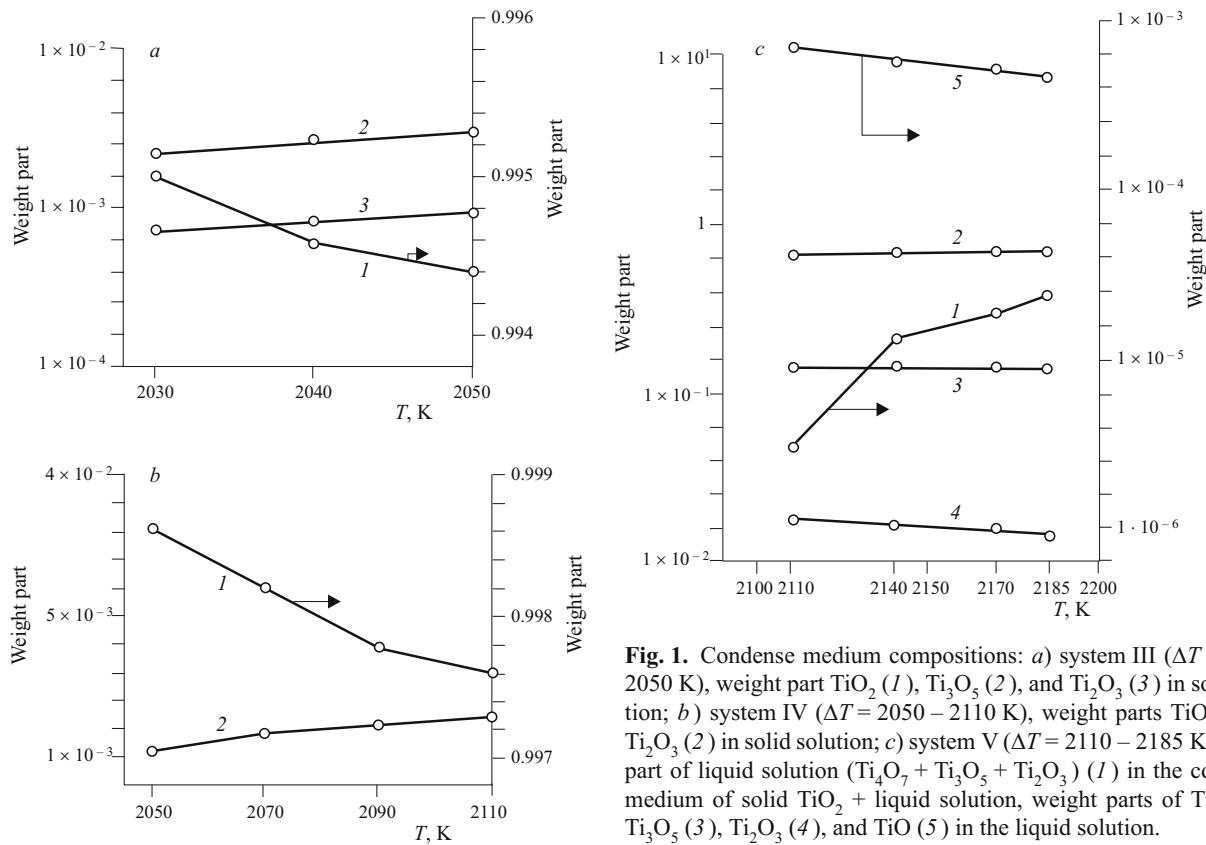

system V,  $\Delta T = 2110–2185$  K – solid phase  $\text{TiO}_2$  and liquid solution ( $\text{Ti}_4\text{O}_7 + \text{TiO} + \text{Ti}_3\text{O}_5 + \text{Ti}_2\text{O}_3$ );

system VI,  $\Delta T = 2185–2485$  K – liquid solution (melt) of all titanium oxides.

The volatile components of the gaseous phase that were taken into account were  $\text{TiO}_2$ ,  $\text{TiO}$ ,  $\text{Ti}$ ,  $\text{O}_2$ , and  $\text{O}$  [4, 6]. Their thermodynamic characteristics are specified in [7]. The calculation has been performed according to the method described in [7, 8]. The software used was the ASTRA-4 package with the ASTRA.BAS database [7].

*Condensed medium.* It was found that the weight part of the most thermally stable  $\text{TiO}_2$  remains prevalent in the con-

**Fig. 1.** Condense medium compositions: a) system III ( $\Delta T = 2030 - 2050$  K), weight part  $\text{TiO}_2$  (1),  $\text{Ti}_3\text{O}_5$  (2), and  $\text{Ti}_2\text{O}_3$  (3) in solid solution; b) system IV ( $\Delta T = 2050 - 2110$  K), weight parts  $\text{TiO}$  (1) and  $\text{Ti}_2\text{O}_3$  (2) in solid solution; c) system V ( $\Delta T = 2110 - 2185$  K), weight part of liquid solution ( $\text{Ti}_4\text{O}_7 + \text{Ti}_3\text{O}_5 + \text{Ti}_2\text{O}_3$ ) (1) in the condensed medium of solid  $\text{TiO}_2$  + liquid solution, weight parts of  $\text{Ti}_4\text{O}_7$  (2),  $\text{Ti}_3\text{O}_5$  (3),  $\text{Ti}_2\text{O}_3$  (4), and  $\text{TiO}$  (5) in the liquid solution.

densed medium in the whole temperature range. At  $\Delta T = 1462 - 2485$  K it varies from 1 to approximately 0.986. At the same time, the analysis of particular systems has revealed several nonstandard peculiarities in the variations of the medium composition.

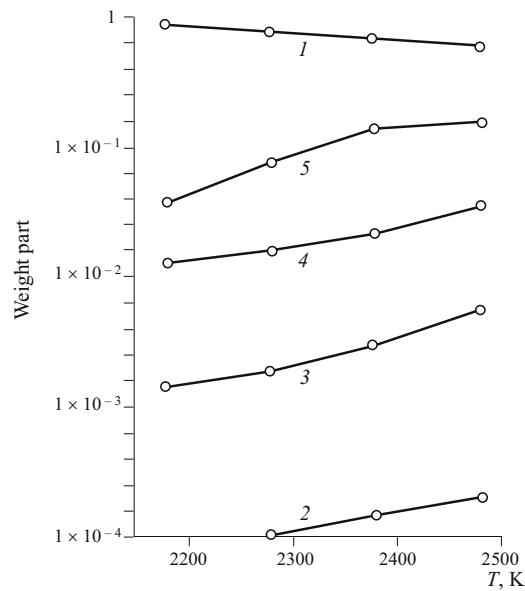

**System I** ( $\Delta T = 300 - 1960$  K). Calculations have shown that at a temperature below 1462 K the total weight parts of the oxides ( $\text{Ti}_4\text{O}_7$ ,  $\text{Ti}_3\text{O}_5$ ,  $\text{TiO}$ ,  $\text{Ti}_2\text{O}_3$ ) constitute less than  $10^{-4}$ ; with temperature increasing in the interval of 1462 – 1960 K they grow insignificantly but do not exceed  $10^{-2}$ .

**System II** ( $\Delta T = 1960 - 2030$  K). The liquid phase  $\text{Ti}_4\text{O}_7$  is not formed. The weight parts of the oxides ( $\text{Ti}_3\text{O}_5$ ,  $\text{Ti}_2\text{O}_3$ ,  $\text{TiO}$ ) in the solid solution increase with increasing temperature, but their total weight parts do not exceed  $10^{-2}$  either.

**System III** ( $\Delta T = 2030 - 2050$  K). The liquid solution ( $\text{Ti}_4\text{O}_7 + \text{TiO}$ ) is not formed. A rise in temperature increases the weight parts of  $\text{Ti}_3\text{O}_5$  and  $\text{Ti}_2\text{O}_3$  in the solid solution, whereas the weight part of  $\text{TiO}_2$  decreases (Fig. 1).

**System IV** ( $\Delta T = 2050 - 2110$  K). The liquid solution ( $\text{Ti}_4\text{O}_7 + \text{TiO} + \text{Ti}_3\text{O}_5$ ) is not formed. With increasing temperature the weight part of  $\text{Ti}_2\text{O}_3$  in the solid solution grows and the weight part of  $\text{TiO}_2$  decreases (Fig. 1).

**System V** ( $\Delta T = 2110 - 2185$  K). The simultaneous presence of the solid phase  $\text{TiO}_2$  and the liquid solution ( $\text{Ti}_4\text{O}_7 + \text{TiO} + \text{Ti}_3\text{O}_5 + \text{Ti}_2\text{O}_3$ ) was identified. The weight part of the latter in the condensed medium at 2110 – 2185 K grows from about  $5 \times 10^{-6}$  to about  $5.4 \times 10^{-5}$ . The weight parts of  $\text{TiO}$  and  $\text{Ti}_2\text{O}_3$  in the solution decrease with increasing

**Fig. 2.** Weight parts of  $\text{TiO}_2$  (1),  $\text{TiO}$  (2),  $\text{Ti}_2\text{O}_3$  (3),  $\text{Ti}_3\text{O}_5$  (4), and  $\text{Ti}_4\text{O}_7$  (5) in liquid solution in system VI ( $\Delta T = 2185 - 2485$  K).

temperature, the weight part of  $\text{Ti}_4\text{O}_7$  grows, and the weight part of  $\text{Ti}_3\text{O}_5$  virtually does not change (Fig. 1).

**System VI** ( $\Delta T = 2185 - 2485$  K). As the temperature increases, the weight part of  $\text{TiO}_2$  in the liquid solution perceptibly decreases, whereas the weight parts of the other oxides

TABLE 1

1960 – 2030	4.696	20,227	3.404	13,778	10.570	58,636	9.555	43,352	7.914	30,682
2030 – 2050	4.715	20,270	3.385	13,750	10.591	58,666	9.761	42,958	7.844	30,541
2050 – 2110	4.479	20,195	2.969	13,713	10.975	58,637	10.030	43,100	7.805	30,461
2110 – 2185	13.724	42,978	21.453	59,266	— 7.543	13,010	0.746	20,235	7.767	30,380
2185 – 2485	3.810	17,722	1.599	8693	10.290	59,184	8.637	41,091	5.726	25,941

Note. The values of  $p_i$  in the computations are in MPa.

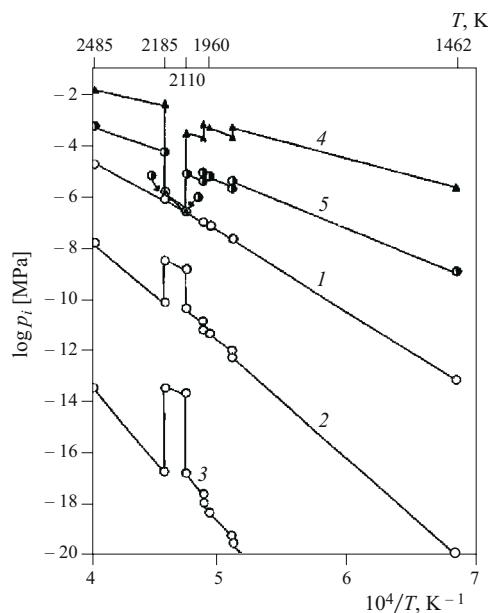

Fig. 3. Dependences of partial pressures of the gaseous phase components  $X$  [1)  $\{\text{TiO}_2\}$ , 2)  $\{\text{TiO}\}$ , 3)  $\{\text{Ti}\}$ , 4)  $\{\text{O}_2\}$ , and 5)  $\{\text{O}\}$ ] formed under heating titanium dioxide in an argon medium in the temperature interval of 1462 – 2485 K.

$(\text{Ti}_4\text{O}_7, \text{Ti}_3\text{O}_5, \text{TiO}, \text{Ti}_2\text{O}_3)$  as the solution components increase (Fig. 2).

Thus, the thermodynamic analysis indicates that the condensed medium formed in heating titanium dioxide in argon is not represented only by the initial oxide ( $\text{TiO}_2$ ) in the solid or liquid state. For instance, at temperatures preceding the melting (system V) we have identified the range of coexistence of solid  $\text{TiO}_2$  and the liquid solution consisting of different titanium oxides, which can be interpreted as an “extended” effect of titanium dioxide premelting.

*The gaseous phase.* The equations for estimating the partial pressures of the main components of the gaseous phase under heating initial titanium dioxide in an argon medium are given in Table 1. The temperature dependences of partial pressures  $p_i$  of the gaseous phase components  $\{\text{O}_2\}$ ,  $\{\text{O}\}$ ,  $\{\text{TiO}\}$ ,  $\{\text{TiO}_2\}$ , and  $\{\text{Ti}\}$  (the computations are performed based on the equations given in Table 1) are presented in Fig. 3. It can be seen that with increasing temperature the values  $p_i$  actually grow monotonically. An exception is the

interval  $\Delta T = 2030 – 2185$  K, where we observe a decrease in partial pressure of the gaseous phase components  $\{\text{O}_2\}$  and  $\{\text{O}\}$  and the growth in the  $p_i$  of the gaseous components  $\text{TiO}$  and  $\text{Ti}$ . This effect is the most perceptible in the range of premelting of solid  $\text{TiO}_2$  ( $\Delta T = 2110 – 2185$  K), i.e., under the temperatures of the coexistence of the solid phase  $\text{TiO}_2$  and the liquid solution ( $\text{Ti}_4\text{O}_7 + \text{TiO} + \text{Ti}_3\text{O}_5 + \text{Ti}_2\text{O}_3 + \text{TiO}_2$ ).

Thus, the method of thermodynamic modeling in a wide temperature interval (300 – 2485 K) was used to identify the compositions of the condensed medium and the gaseous phase under heating  $\text{TiO}_2$  in an inert atmosphere taking into account the possibility of formation of solid and liquid solutions with the participation of other titanium oxides. The range of coexistence of the solid phase  $\text{TiO}_2$  with the liquid solution ( $\text{Ti}_4\text{O}_7 + \text{TiO} + \text{Ti}_3\text{O}_5 + \text{Ti}_2\text{O}_3$ ) was identified. The obtained results can be useful for describing chemical transformations in the high-temperature synthesis of complex ceramics with the participation of titanium dioxide and for analyzing the composition of these ceramics.

*The study was performed with financial support of the Russian Fund for Fundamental Research, projects 04-03-33109 and 05-08-01279.*
